### **Artificial Cells Produce Parts of Viruses for Safe Studies**

*The Weizmann Institute of Science group demonstrated the production of protein assembly lines on a silicon chip*

Scientists searching for better diagnostic tests, drugs or vaccines against a virus must all begin by deciphering the structure of that virus. And when the virus in question is highly pathogenic, investigating, testing or developing these can be quite dangerous. Prof. Roy Bar-Ziv, Staff Scientist Dr. Shirley Shulman Daube, Dr. Ohad Vonshak, a former research student in Bar-Ziv's lab, and current research student Yiftach Divon have an original solution to this obstacle. They demonstrated the production of viral parts within artificial cells.

The cells are micrometer-sized compartments etched into a silicon chip. At the bottom of each compartment, the scientists affixed DNA strands, packing them densely. The edges of the artificial cells were carpeted with receptors that can capture the proteins produced within the cells. To begin with, the scientists flooded their cells with everything needed to make proteins – molecules and enzymes needed to read the DNA information and translate it into proteins. Then, with no further human intervention, the receptor carpet trapped one of the proteins produced in the bottoms of the cells, with the rest of the viral proteins binding to one another, producing structures that the scientists had earlier “programmed” into the system. In this case, they created assorted small parts of a virus that infects bacteria (a bacteriophage).

“We discovered,” says Bar-Ziv, “that we can control the assembly process – both the efficiency and the final products – through the design of the artificial cells. This included the cells’ geometric structure, and the placement and organization of the genes. These all determine which proteins will be produced and, down the line, what will be made from these proteins once they are assembled.”

Vonshak adds: “Since these are miniaturized artificial cells, we can place a great many of them on a single chip. We can alter the design of various cells, so that diverse tasks are performed at different locations on the same chip.”

The features of the system developed at the Weizmann Institute – including the ability to produce different small parts of a single virus at once, could give scientists around the globe a new tool for evaluating tests, drugs and vaccines against that virus. Adds Divon: “And because the artificial parts – even if they faithfully reproduced parts of the virus – do not include the use of actual viruses, they would be especially safe from beginning to end”. “Another possible application”, says Shulman Daube, “might be the development of a chip that could rapidly and efficiently conduct thousands of medical tests all at once”.

Participating in this research were Stefanie Förste, Dr. Sophia Rudolf and Prof. Reinhard Lipowsky from the Max Planck Institute of Colloids and Interfaces in Potsdam, Germany, and David Garenne and Prof. Vincent Noireaux from the University of Minnesota. The research was published today in Nature Nanotechnology.

*Prof. Roy Bar Ziv's research is supported by the Clore Center for Biological Physics; and the Harry Perlman Family*

The Weizmann Institute of Science in Rehovot, Israel, is one of the world's top-ranking multidisciplinary research institutions. Noted for its wide-ranging exploration of the natural and exact sciences, the Institute is home to scientists, students, technicians and supporting staff. Institute research efforts include the search for new ways of fighting disease and hunger, examining leading questions in mathematics and computer science, probing the physics of matter and the universe, creating novel materials and developing new strategies for protecting the environment.

Weizmann Institute news releases are posted on the World Wide Web at
